

EXPERIMENT 3

Name- Laksh Sodhai

Class-D20A

Roll no-64

Aim: Create a Cryptocurrency using Python and perform mining in the Blockchain created.

Theory:

1. Blockchain Overview

A blockchain is a distributed, decentralized digital ledger used to record transactions securely across multiple computers (nodes). Instead of relying on a central authority, every node in the network maintains its own copy of the blockchain.

Each block in the blockchain contains:

- A list of transactions
- A timestamp
- The hash of the previous block
- Its own cryptographic hash

The blocks are linked together using hashes, forming a chain. Any attempt to modify data in a block changes its hash, which breaks the chain and makes tampering easily detectable. This property ensures data integrity, transparency, and immutability.

2. Mining

Mining is the process by which new blocks are added to the blockchain. It involves:

- Collecting pending transactions
- Creating a block header
- Solving a computationally difficult problem known as Proof-of-Work (PoW)

In Proof-of-Work, miners repeatedly change a nonce value to generate a hash that satisfies the network's difficulty requirement (such as leading zeroes). Once a valid hash is found, the block is added to the blockchain and shared with other nodes. As an incentive, miners receive a cryptocurrency reward for their computational effort.

3. Multi-Node Blockchain Network

In this experiment, a multi-node blockchain network is simulated using three nodes running on different ports (5001, 5002, and 5003).

Each node:

- Operates independently
- Maintains its own copy of the blockchain
- Communicates with peer nodes to share newly mined blocks

This setup demonstrates how blockchain achieves decentralization and synchronization without a central server.

4. Consensus Mechanism

To ensure consistency across all nodes, the Longest Chain Rule is used as the consensus mechanism.

When different versions of the blockchain exist, the node accepts the longest valid chain as the correct one. This rule ensures that all nodes eventually agree on a single transaction history, even if temporary differences arise.

5. Transactions and Mining Reward

Transactions in the cryptocurrency system include:

- Sender address
- Receiver address
- Transaction amount

When a block is mined, all pending transactions are added to the block. Additionally, a special transaction is created to reward the miner with newly generated cryptocurrency. This reward mechanism motivates miners to maintain and secure the network.

6. Chain Replacement

The chain replacement process ensures network consistency. When the /replace_chain endpoint is triggered:

- A node requests blockchain data from its peers
- Validates the received chains
- Replaces its own chain if a longer and valid chain is found.

This mechanism helps resolve conflicts and keeps all nodes synchronized.

Code:

```
# Module 2 - Create a Cryptocurrency

# =====#
HadCoin Blockchain Node
# =====#
import datetime import hashlib import
```

```
json from flask import Flask, jsonify,
request import requests

Output:

1)/get_chain

This GET request retrieves the complete blockchain from the node, showing all mined blocks and stored transactions.

The screenshot shows the Postman application interface. At the top, there's a header bar with tabs for Overview, GET http://127.0.0.1:5001/get_chain, and Untitled Request. Below the header, the URL http://127.0.0.1:5001/get_chain is entered in the main search field. The method is set to GET. To the right of the URL, there are buttons for Save, Share, and Send. The 'Send' button is highlighted in blue. Below the URL, there are tabs for Docs, Params, Authorization, Headers (with a green info icon), Body, Scripts, and Settings. The 'Body' tab is selected. Under 'Body', there are options for none, form-data, x-www-form-urlencoded, raw (which is selected), binary, GraphQL, and JSON. To the right of these options are buttons for Schema and Beautify. The main content area shows the response body in JSON format. The JSON object has the following structure:

```
1: {  
2:   "chain": [  
3:     {  
4:       "index": 1,  
5:       "previous_hash": "0",  
6:       "proof": 3,  
7:       "timestamp": "2028-02-13 17:35:04.581315",  
8:       "transactions": []  
9:     }  
10    ],  
11    "length": 1  
12  }  
13  
14  
15
```

At the bottom of the interface, there are tabs for Body, Cookies, Headers (5), Test Results, and a preview section. The status bar at the bottom right indicates a 200 OK response with 6 ms and 290 B.

2)/mine_block

This GET request performs the mining process using Proof-of-Work and adds a new block to the blockchain.

The screenshot shows a POST request to `http://127.0.0.1:5001/mine_block`. The response is a 200 OK status with a JSON payload representing a new blockchain block. The JSON object contains the following fields:

```
{} previous_hash": "290c32e95e615c306a37ec429fb234cbfa6972588adefad51fce0be24a18e9", "proof": 533, "timestamp": "2026-02-13 17:54:49.149715", "transactions": [ { "amount": 1, "to": "Laksh_Sodhiya", "from": "0x440e5e4744a4d0f0a4703207000" } ]
```

3)/is_valid

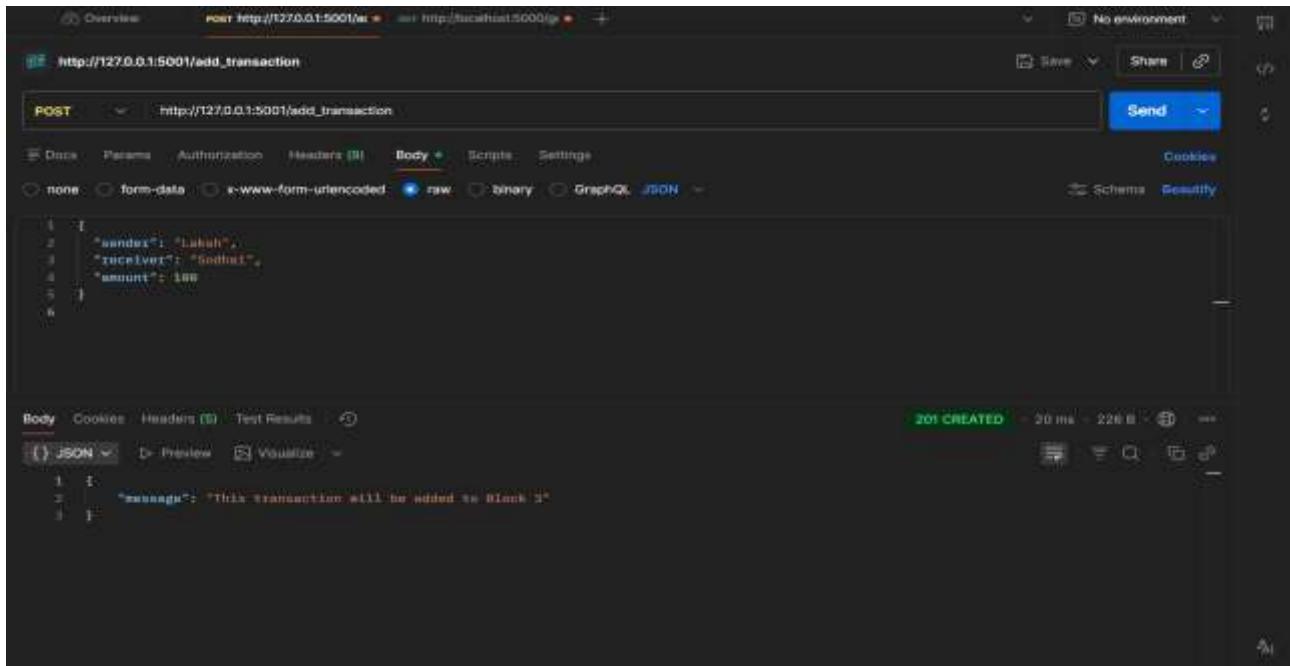

This GET request checks whether the current blockchain is valid and untampered.

The screenshot shows a GET request to `http://127.0.0.1:5001/is_valid`. The response is a 200 OK status with a JSON payload containing the message: "All good. The Blockchain is valid."

```
{ "message": "All good. The Blockchain is valid." }
```

4)/add_transaction

This POST request submits a new transaction (sender, receiver, amount) to be added to the next mined block.

The screenshot shows a Postman interface with the following details:

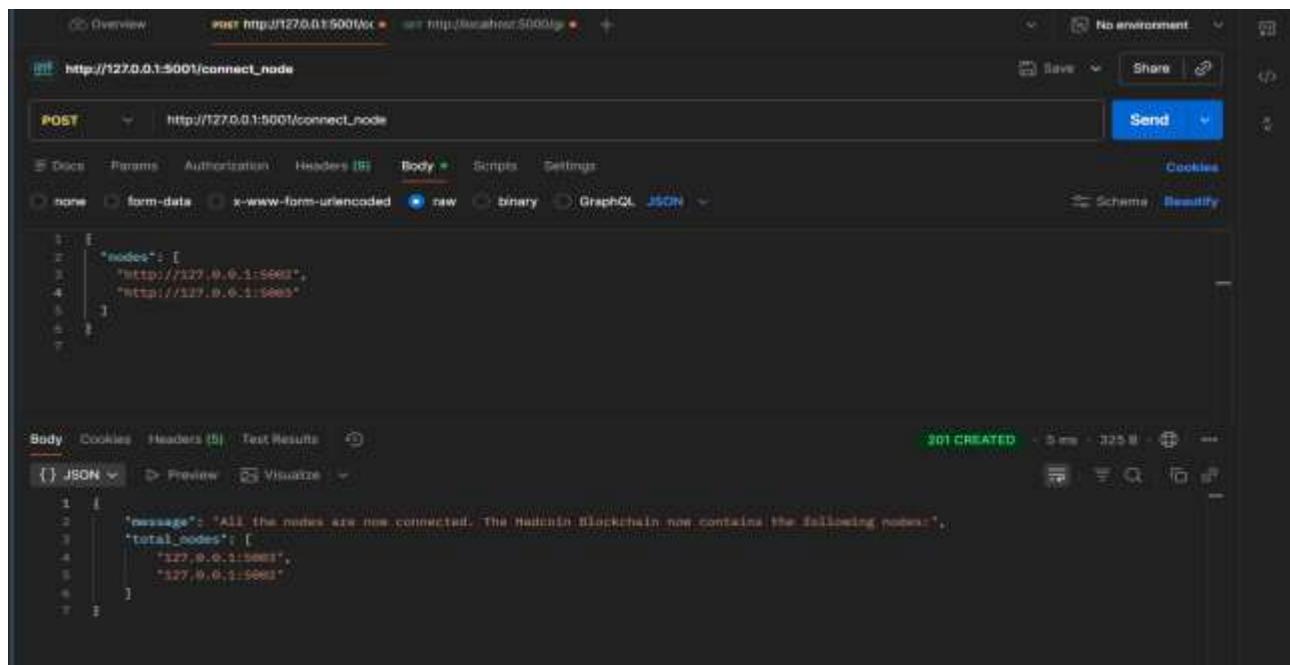

- Request URL:** http://127.0.0.1:5001/add_transaction
- Method:** POST
- Body:** JSON (raw)

```
{  
    "sender": "Lukash",  
    "receiver": "Sodin",  
    "amount": 100  
}
```
- Response Status:** 201 CREATED
- Response Body:**

```
{  
    "message": "This transaction will be added to Block 3"  
}
```

5)/connect_node

This POST request connects the current node with other peer nodes in the blockchain network.

The screenshot shows a Postman interface with the following details:

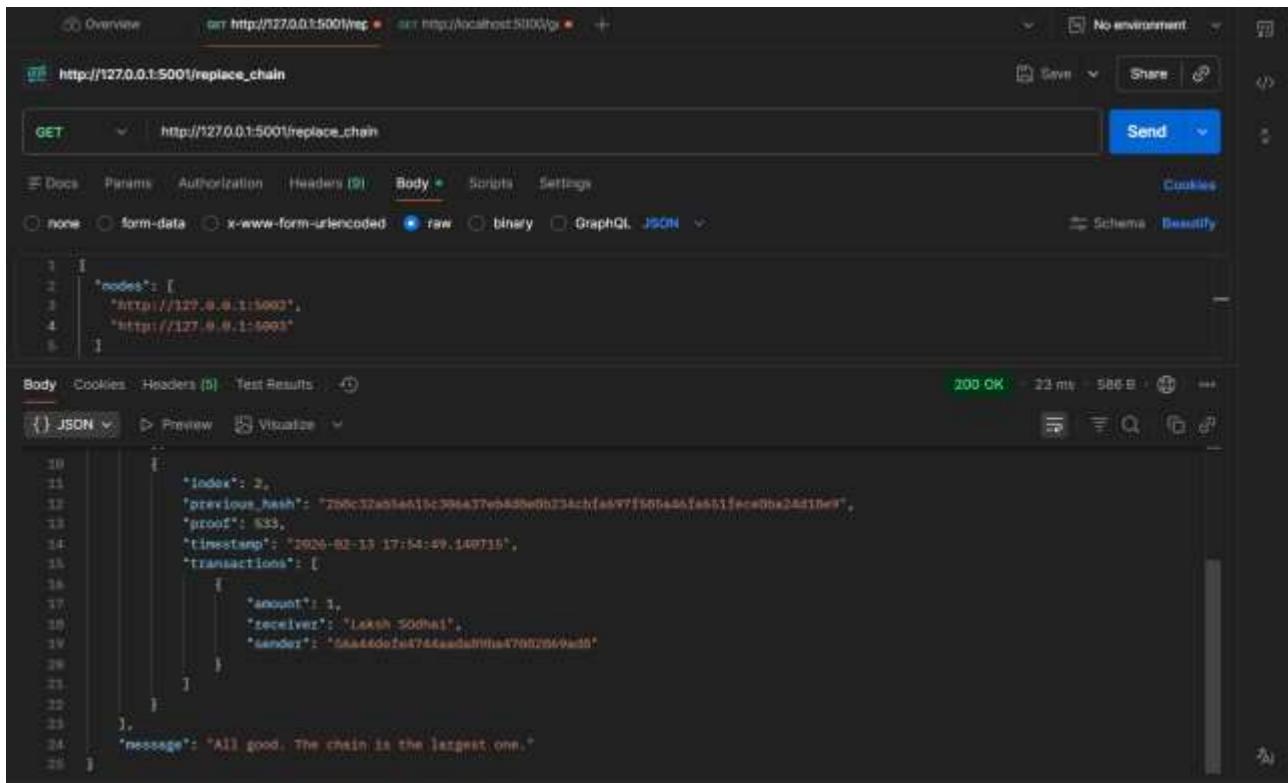

- Request URL:** http://127.0.0.1:5001/connect_node
- Method:** POST
- Body:** JSON (raw)

```
{  
    "nodes": [  
        "http://127.0.0.1:5002",  
        "http://127.0.0.1:5003"  
    ]  
}
```
- Response Status:** 201 CREATED
- Response Body:**

```
{  
    "message": "All the nodes are now connected. The Blockchain now contains the following nodes:",  
    "total_nodes": [  
        "127.0.0.1:5002",  
        "127.0.0.1:5003"  
    ]  
}
```

6)/replace_chain

This GET request checks all connected peer nodes and replaces the current blockchain with the longest valid chain, ensuring network-wide consistency.

```
1 {
2     "nodes": [
3         "http://127.0.0.1:5002",
4         "http://127.0.0.1:5003"
5     ]
6 }
```

```
1 {
2     "index": 2,
3     "previous_hash": "200c32a054615c306437e6d5e01234cb1a97f507a461e6115cc00x24310e",
4     "proof": 633,
5     "timestamp": "2024-02-13 17:54:49.140715",
6     "transactions": [
7         {
8             "amount": 1,
9             "receiver": "Laksh Sodhai",
10            "sender": "GauravDixit786caed0ff1847002969e0"
11        }
12    ],
13    "message": "All good. The chain is the longest one."
14 }
```

Conclusion:

In this experiment, a basic cryptocurrency system was designed and implemented using Python by applying fundamental blockchain principles such as block generation, cryptographic hashing, Proof-of-Work mining, transaction processing, and decentralized networking. A Flask-based framework was used to enable communication between multiple nodes, with each node maintaining its own copy of the blockchain ledger.

The mining process required solving the Proof-of-Work challenge, after which new blocks were added to the chain and miners received rewards. The system also supported transaction validation and inclusion of verified transactions into newly mined blocks. Through this implementation, the experiment offered hands-on insight into the functioning of blockchain technology, demonstrating how consensus, decentralization, and mining together enable the secure operation of cryptocurrencies in distributed environments.
